PRESENTACION

Los estudios de Operación y Seguridad del Sistema de Embalses de Valdesia fueron ejecutados conjuntamente por el Instituto Nacional de Recursos Hidráulicos (INDRHI) de la República Dominicana, la Universidad del Estado de Colorado (CSU) y el Instituto Interamericano de Cooperación para la Agricultura (IICA) a través del Contrato IICA/INDRHI/CSU firmado el 6 de abril de 1984. Los estudios se iniciaron el 6 de agosto de 1984 y finalizaron el 31 de agosto de 1986.

Los estudios fueron financiados por el INDRHI a través del préstamo 1655-DO del Banco Mundial.

La ejecución de los estudios se desarrolló en seis áreas:

- a) Estudios Hidrológicos
- b) Operación Normal
- c) Operación de Emergencia
- d) Inspección, Mantenimiento y Seguridad de Presas
- e) Organización para la Operación del Sistema de Embalses
- f) Entrenamiento y Transferencia de Tecnología

En este documento se incluye parte del material técnico del Informe Final, el cual consta de los siguientes volúmenes:

- Resumen
- Estudios Hidrológicos
- Operación Normal
- Estudios de Operación de Crecidas
- Estudios de Inspección, Mantenimiento y Seguridad de Presas
- Organización y Funciones para la Operación del Sistema de Embalses de Valdesia.

- Transferencia de Tecnología y Capacitación.
- Plan de Operación de Emergencia para el Sistema de Embalses de Valdesia.
- Plan de Operación Normal para el Sistema de Embalses de Valdesia:
(1) Riego y Energía, (2) Control de Crecidas.
- Manuales de Operación de Modelos Computarizados para la Operación Normal del Sistema de Embalses.
- Manual de Usuario de Modelos de Sistemas Hidrológicos.

1. ESTUDIO DE OPERACION NORMAL DEL SISTEMA DE VALDESLA

Se condujo un análisis comprensivo de la operación del Embalse de Valdesia en la República Dominicana para condiciones de operación normal como se informó en el Volumen II: Operación Normal (Labadie et al., 1986) de los Estudios de Operación y Seguridad del Embalse de Valdesia. El énfasis se concentró en el desarrollo de estrategias integradas que incorporan el embalse e hidroeléctrica de Valdesia, el embalse Las Barrias aguas abajo y los canales principales Marcos A. Cabral y Nizao-Najayo que abastecen a más de 10000 ha de área irrigada como se muestra en la Figura 1. El objetivo es producir procedimientos operacionales de carácter práctico que maximicen la producción de energía de la hidroeléctrica a largo plazo, sujeto a la satisfacción de las necesidades de riego con un riesgo mínimo. El análisis de la operación histórica del sistema revela que no se han implementado reglas consistentes de operación como indican las deficiencias significativas de riego y altas variaciones en las horas de turbinado y producción de energía.

Se seleccionó una aproximación jerárquica en la cual se desarrollaron curvas-guía para almacenamiento óptimo mensual usando programación dinámica estocástica (Programa CSUDP) y luego usadas como metas en un modelo de simulación de redes llamado MODSIM, el cual se puede usar en forma interactiva en base semanal por el personal de operaciones como soporte para las decisiones en tiempo real. La documentación completa de los Programas CSUDP y MODSIM se encuentra en el informe "Manuales de Operación de Modelos Computarizados para la Operación Normal de Sistemas de Embalses" (Labadie et al., 1986). Además, se proveen curvas-guía diarias, principalmente para la operación de energía para determinar la carga óptima de las turbinas en la planta para maximizar eficiencia.

Las metas mensuales de los caudales que entran al embalse de Valdesia y están condicionadas sobre un rango amplio de niveles de almacenamiento y caudales precedentes para cada mes. El análisis semanal puede hacer uso de caudales pronosticados, demandas de riego y necesidades de riego en tiempo real.

Figura 1. Sistema de Embalses de Valdesia

La llave para una operación óptima del sistema de Valdesia está en la sincronización de los usos del sistema, para riego y energía. Esto requiere diagnósticos precisos de las necesidades reales de agua para los cultivos y estrategias operacionales que minimicen tanto la deficiencia como el mal uso. Las necesidades de agua por los cultivos son estimadas usando el método modificado de Penman. Aunque la información meteorológica fue insuficiente para el uso de este método, aún así se prefirió sobre otras técnicas. Su uso puede, también, crear ambiente para mejorar la recolección de información y su proceso. La contribución de la precipitación a los cultivos se estimó usando el método desarrollado por Morel-Seytoux y Restrepo (1985). Además de las informaciones hidrológicas, meteorológicas y agronómicas, se realizó un intento de estimativa de los costos básicos y beneficios asociados con la operación del sistema de Valdesia. Estos datos fueron empleados para definir el beneficio potencial de la mejoría de la operación del sistema de Valdesia, en contraste con las reglas históricas.

Con el objeto de ganar experiencia en el uso de los modelos para operaciones futuras, se realizaron ejercicios de calibración tanto para modelos mensuales como semanales. Para este proyecto se desarrolló una gran base de datos lo cual significó un trabajo laborioso de entrada de datos y uso de la misma para calibración y desarrollo de las reglas óptimas de operación. En la Tabla 1 se presenta una lista de la base de datos computarizada desarrollada para este estudio en la Universidad del Estado de Colorado. Los resultados de calibración fueron considerados satisfactorios para los propósitos de este proyecto y los modelos calibrados se consideran como herramientas operacionales viables para el sistema Valdesia. En el futuro y a medida que cambie la situación se deberán actualizar los parámetros y entradas del modelo.

Mediante el Programa CSUDP se desarrollaron curvas-guías óptimas mensuales para almacenamiento considerando la carga óptima de las dos turbinas de la hidroeléctrica. Es decir, para varias combinaciones discretas de carga-descarga se desarrolló un análisis de preoptimización mediante el cual se determinó como se debería cargar cada turbina con el objeto de maximizar la eficiencia global y por lo tanto la producción de energía. Esta tabla de carga óptima

deberá ser útil para la operación diaria del sistema y se presenta en el Anexo A.

Con el desarrollo de las curvas-guías óptimas mensuales para almacenamiento usando el programa CSUDP, se intentó probarlas a través de la definición de los riesgos a largo plazo asociados con el cumplimiento de las demandas de riego y mantenimiento de varios niveles de salidas de energía y potencia.

Se desarrolló el análisis de Monte Carlo para 400 años de información sintética generada para caudales y horas de generación de las turbinas. Esta información se introdujo en el Programa MODSIM (Simulación de redes de flujo), empleando las curvas-guías óptimas para almacenamiento generadas por el CSUDP. Las horas de generación por turbina se incluyeron en el modelo estocástico bivariado debido a su alta variabilidad y gran correlación con caudales. Los resultados fueron extremadamente promisorios para abastecimiento de riego, con riesgo virtualmente igual a cero para deficiencias de agua.

Mayores pruebas de las reglas óptimas de operación por programación dinámica se desarrollaron usando el período histórico desde el Huracán David. En este caso se usó un intervalo de tiempo semanal. Se determinó que en vez de usar horas de generación histórica, como un reflejo de la demanda de energía, era más razonable usar la salida de potencia como un medio de comparación. La razón para ello está en que el examen de las operaciones históricas del sistema revela amplias variaciones de los niveles de horas de generación de las turbinas en contraste con los niveles relativamente estables de los niveles de capacidad de potencia de alrededor de 30 MW. Esto indica que los operadores del sistema intentan estabilizar la capacidad de potencia tanto como es posible para integración en la red de distribución de potencia del país, lo cual por su vez, a menudo impone horas de generación, particularmente para períodos donde los caudales son altos y por lo tanto las descargas también son substanciales.

Los resultados de esta comparación fueron extremadamente promisorios, con las reglas óptimas de operación (programación dinámica) produciendo 23% más

más potencia y sobre 11% más de energía, sin producir deficiencias de riego. Un análisis de los excesos de los aliviaderos en Las Barrias, resultante de las reglas óptimas de programación dinámica indicó que mediante el almacenamiento de algún exceso de agua sobre las curvas-guías de programación dinámica y luego liberando el agua más tarde, se podía mantener por lo menos 10% de aumento en el abastecimiento de riego con una alta confiabilidad. A partir de un análisis económico preliminar, el cual supuso que se aplicaría exceso de agua para regar más tierra a la cabeza y cola de los canales, se estimó que un retorno adicional de RD\$3.69 millones por año se podía obtener como resultado de la aplicación de las curvas-guías óptimas para almacenamiento (programación dinámica) sobre el período histórico. Sumando el beneficio estimado de aumento en la producción de energía, el beneficio total habría sido de RD\$7.93 millones por año.

2. REVISION DE LOS PROCEDIMIENTOS DE OPERACION NORMAL

Se usa una aproximación de descomposición temporal de las estrategias de operación normal para el sistema de Valdesia, la cual se inicia con el desarrollo de políticas óptimas de retroalimentación para cada calendario mensual para el embalse de Valdesia que maximice la producción de energía sujeta a la satisfacción de las necesidades de riego (Figura 2). Una aproximación de optimización totalmente dinámica que emplea programación dinámica estocástica (Programa CSUDP) se utiliza a nivel mensual, la cual requiere de las siguientes informaciones de entrada:

1. Probabilidades de transición mes a mes que describen las características estocásticas de los caudales del río Nizao al Embalse Valdesia. Puesto que los caudales son altamente aleatorios, se necesita una alternativa estocástica explícita para desarrollar reglas operacionales que maximicen el uso beneficioso a largo plazo del sistema.

Figura 2. Aproximación jerárquica para el óptimo desarrollo de las reglas de operación normal.

2. Horas de producción hidroeléctrica, lo cual ha sido altamente aleatorio en el pasado debido a: períodos variables de los picos diarios de carga y uso del sistema para carga de base, como necesidad debida a las deficiencias o fallas en varias partes de la red de potencia de República Dominicana.
3. Características físicas del sistema, incluyendo características de la planta hidroeléctrica, capacidades del embalse, tablas de área superficial-carga-capacidad, etc.
4. Demandas de riego estimadas usando el modelo modificado de Penman.

Se espera que la optimización por programación dinámica necesite sólo de corridas adicionales si llega a ser evidente que los valores actuales de uno o mas de las informaciones de entrada, antes mencionadas, no son válidas o necesitan ajuste. Las reglas operacionales generadas por la optimización especifican niveles de almacenamiento óptimos al fin de mes, condicionados a los niveles iniciales de almacenamiento y períodos previos de caudales para considerar la persistencia de caudales mensuales sucesivos. Estos tipos de reglas de retroalimentación son esenciales debido a que representan líneas-guías óptimas para una gran variedad de almacenamiento y condiciones de caudales que pueden existir en cualquier tiempo, mas que una regla óptima inflexible de circuito abierto.

Luego, las curvas guías óptimas de los análisis mensuales se pueden utilizar para la operación mensual en tiempo real del sistema. Se emplea una red detallada del modelo de simulación (Programa MODSIM) para determinar la alocación óptima de agua en el sistema de Valdesia para la hidroeléctrica y los varios sectores de riego del sistema, mientras se intentaba de cumplir con las líneas-guías mensuales. El procedimientos permite la oportunidad de incluir información de pronóstico de caudales a nivel semanal. Estos pronósticos se pueden actualizar en base semanal y correr el modelo para acomodar las condiciones cambiantes así como se monitorea el desempeño del sistema. La meta

es que el modelo de simulación de redes llegue a ser una herramienta operacional en tiempo real que sea manejable y fácil de usar por los operadores del sistema. Las curvas-guías y modelos de computador son definidos como mecanismos de soporte solo para los operadores del sistema. El uso de metas semanales y mensuales permiten flexibilidad en las operaciones diarias. Ellas son consideradas como metas solamente y los operadores son libres para desviarse de las mismas como sea necesario y de acuerdo con la experiencia.

3. CURVAS GUIAS PARA LA OPERACION OPTIMA MENSUAL

Las reglas de operación normal para este sistema son diseñadas para guiar la operación del Embalse Valdesia para cumplir con los objetivos de abastecimiento de agua y energía. Sin considerar el control de retroalimentación en tiempo real, generalmente se desarrolla un conjunto de curvas guías para operar durante la vida del embalse. En vez de generar curvas simples de reglas operacionales, este estudio llega a una etapa mas avanzada con la incorporación de las condiciones hidrológicas actuales (caudal del mes anterior) y el rango completo de posibles inicios de niveles de almacenamiento en el embalse en las líneas guías de operación normal.

Con el propósito de flexibilizar la operación, se desarrolló una familia de curvas metas de operación de almacenamiento condicionadas sobre niveles discretos de caudales previos de Valdesia del análisis de programación dinámica estocástica usando el Programa CSUDP. La regla operacional óptima correspondiente (estacionaria) se muestran en el Anexo B. Los valores tabulados correspondientes a estas reglas operacionales se presentan en el Anexo C, si se consideran conveniente utilizar.

4. EL PROGRAMA MODSIM Y SU EJECUCION

Las reglas operacionales óptimas de la programación dinámica se introducen en el Programa MODSIM para desarrollar estrategias operacionales semanales en

tiempo real para el sistema de Valdesia. Las reglas operacionales de programación dinámica definen curvas-guías mensuales de almacenamiento, las cuales son interpoladas en niveles semanales. Aplicando la estrategia jerárquica mostrada en la Figura 2, se pueden introducir en el MODSIM los valores pronosticados de caudales, demandas de riego y necesidades de energía, y luego actualizarlos en base semanal.

La Figura 3 muestra la configuración de nudos para uso en tiempo real semanal en el Programa MODSIM. Esto incluye cada sector de riego para los cuales se preparan las estimaciones de demandas de riego.

En la Figura 4 se muestra la parte de impresión "echo" del archivo de datos de entrada ORGANIZ para la configuración mostrada en la Figura 3. La mayoría de las informaciones en este archivo se relacionan con las características físicas que no cambian del sistema, aunque se requieren algunos cambios. Obsérvese que la capacidad de Las Barrias se fijó en 3 millones de metros cúbicos ($3000 \times 10^3 \text{ m}^3$), lo cual es menor que la capacidad de 6.05 millones de metros cúbicos empleada durante la calibración del modelo. Se usa este nivel en consideración a que representa la capacidad efectiva de conservación del embalse, arriba de la cual hay peligro de vertir al río Nizao. En base semanal, los volúmenes iniciales de almacenamiento para Valdesia y Las Barrias tienen que ser cambiados en este archivo, ya que ellos cambian semana por semana. Una explicación completa de como hacer esto se incluye en este Manual.

Las capacidades de conexión (link capacities) en el Canal se basan en la capacidad máxima del canal en la cabecera del canal principal. La razón para ello está en que en lugar de introducir pérdidas en el canal para cada canal considerado en el Programa MODSIM, se ajustaron las demandas de riego para cada sector para considerar el agua requerida en la cabecera del canal para satisfacer las necesidades de agua por los cultivos en ese sector, y todas las pérdidas intermedias e ineficiencias de aplicación. Trabajos futuros pueden emplear necesidades reales de los cultivos como demandas en el Programa MODSIM y luego incluir directamente los coeficientes de pérdidas en el canal

Figura 3. Configuración de Nodo-Conexión para el Sistema de Valdesia para operación semanal en tiempo real.

Figura 4. Impresión "echo" del archivo de datos de entrada, llamado ORGANIZ, para el MODSIM.

y eficiencias de aplicación en los datos de entrada del modelo. La versión actual del MODSIM es capaz de analizar el sistema de riego con cualquiera de las dos alternativas.

La sección siguiente de la impresión "echo" lista en el orden de las prioridades de las demandas del sistema. Las demandas actuales se leen de un archivo diferente llamado ADATA. La revisión/corrección de este archivo, también, se explica en este Manual. Cada modo de demanda debe recibir un número de prioridad, entre 1 y 99, con el valor menor representando la más alta prioridad. Estos factores de ordenamiento son traducidos en costos negativos C_{ij} (realmente, beneficios) y son introducidos en el Modelo. Los detalles de como esto se realiza en el MODSIM se encuentra en el volumen "Manuales de Operación de Modelos Computarizados para la Operación Normal de Sistemas de Embalses" (Labadie et al, 1986). En verdad, estos no son costos absolutos y solo sirven para priorizar que sector debe recibir agua primero. Se sugiere que los operadores asignen números entre 10 y 30 para las demandas, ordenados de tal manera que refleje cuales sectores están en mayor necesidad de agua en el período considerado. En este ejemplo se puede ver que todas las demandas recibieron una prioridad 10 excepto para la demanda llamada Ecológica la cual recibió un número de prioridad 99. Esto significa que ella recibe el agua que sobra después de cumplir con las necesidades de riego y energía.

Continuando con la impresión "echo", la próxima información se relaciona con las metas de niveles de almacenamiento del embalse y sus prioridades. A los embalses se les asignó una factor de orden de prioridad entre 1 y 99. En este ejemplo, el embalse Valdesia recibió un número de 40, lo cual significa que sólo después de cumplir todas las demandas de riego, el modelo intentará llegar a la meta de niveles de almacenamiento provista por el análisis estocástico de programación dinámica. Las fracciones de distribución semanal que se muestran para cada embalse de los niveles deseados de almacenamiento de las curvas-guías representados como la relación del almacenamiento de la curva-guía dividido por la capacidad máxima del embalse. Durante la estación de

crecidas, estas metas reflejarán la imposición de la acumulación de la crecida en el embalse durante estos períodos. Mas adelante se dá una completa descripción de como las curvas guías óptimas mensuales de programación dinámica se interpolan en niveles semanales e incluídas en este archivo de informaciones en tiempo real. Obsérvese que al embalse Las Barrias se le dá una prioridad de 50 lo cual significa que solamente agua extra del sistema se traspasa en este embalse de semana a semana. La información restante en la impresión "echo" se relaciona a los datos físicos del embalse que presumiblemente permanecerá inalterable.

Un archivo de informaciones adicionales llamado ADATA debe ser preparado por los operadores del sistema, el cual incluye:

1. Pronósticos semanales de caudales
2. Demandas semanales de riego
3. Tasas netas semanales de evaporación
4. Horas semanales de generación de las turbinas para cumplir con la demanda de energía.

Para accesar estos datos, el usuario puede basarse en pronósticos o valores típicos históricos para ese período. Se recomienda que los operadores traten con varias alternativas diferentes de pronósticos y observan el impacto sobre las reglas de operación. La preparación del archivo ADATA se obtiene a través de un proceso interactivo fácil el cual se describe en este manual.

Se espera que los operadores hagan varias corridas con el MODSIM en base semanal. Por ejemplo, la información inicial de horas de generación de las turbinas puede resultar en menor potencia o energía que la deseada; en cuyo caso las horas pueden ser ajustadas y el modelo se corre nuevamente hasta que se obtengan los criterios deseados de potencia y energía.

Durante períodos secos, es probable que ocurran algunas deficiencias. Con las prioridades usadas en el ejemplo de impresión "echo" de la Figura 3, el

modelo primero intentará cumplir con las demandas de riego, lo cual puede resultar en niveles y descargas del embalse Valdesia, y por lo tanto producción de energía más baja que la deseada. Para propósitos comparativos, se puede realizar un análisis de compromiso (tradeoff) donde la prioridad de Valdesia se cambie a, por ejemplo, 5. Esto significa que el modelo trata de encontrar primero las metas de almacenamiento y solo el agua sobrante se usa para cumplir con las demandas de riego. Es probable que en esta corrida ocurran grandes deficiencias de riego pero la producción de energía aumentará.

Obviamente, en estos casos se recurre a compromisos. Se pueden seleccionar ciertos sectores e imponerles una deficiencia temporal a través del aumento de su número de prioridad, por ejemplo 60 y colocándole a Valdesia 50. De esta forma, las deficiencias de riego se pueden controlar y balancear con las deficiencias de energía.

5. PASOS EN EL ANALISIS DE LA OPERACION NORMAL SEMANAL

Los siguientes pasos deben ser implementados regularmente en base semanal:

1. Si la semana actual es la primera semana del mes, obtener los niveles de almacenamiento del embalse Valdesia en MSNM. Estos datos se pueden convertir a unidades de almacenamiento en MMC (Millones de metros cúbicos) usando la Tabla 2 ó Figura 5. También, obténgase estimados de caudales totales durante el mes precedente en M^3/S .
2. Para cualquier semana del mes, obtener los niveles actuales de almacenamiento en los embalses de Valdesia y Las Barrias. Los datos de la Tabla 3 se pueden interpolar para dar los volúmenes de almacenamiento usando la información de MSNM de Las Barrias.
3. Inspeccione las Curvas-guías para almacenamiento óptimo del Anexo B (forma gráfica) o Anexo C (forma tabular) y seleccione las curvas para el mes actual (en análisis). Con la forma gráfica, entre en la abscisa con el volumen de almacenamiento al inicio del mes en el Embalse de Valdesia y muévase a la curva apropiada, lo mas próximo al caudal del mes anterior. En algunos casos se puede requerir interpolación.

Tabla 2. Relación Elevación-Area-Volumen
 para el Embalse de Valdesia
 (Fuente: CDE)

Elevación (M.S.N.M.)	Área ($10^3 M^2$)	Volumen	
		Original	Después de Mayo 1981

Tabla 3. Relaciones Elevación-Area-Volumen
 para el Embalse Las Barrias
 (Fuente: CDE)

Elevación (M.S.N.M)	Área (10^3 m^2)	Volumen (10^3 m^3)
69	0	0
70	52	50
72	190	240
73	310	450
74	460	800
75	640	1400
76	805	2100
77*	910	3000
78	1000	4000
80	1140	6050

* Capacidad máxima sin verter en el aliviadero

4. Muévase horizontalmente a la ordenada y obtenga la meta del nivel óptimo de almacenamiento al final del mes.
5. Marcando el volumen de almacenamiento en el inicio del mes actual (en análisis) en la ordenada, divida la línea en cuatro segmentos iguales entre los niveles de inicio y fin del mes, lo cual corresponde a la interpolación linear de las metas de almacenamiento semanal. Si la semana actual (en análisis) no es la primera del mes, reemplace la meta de almacenamiento de la semana anterior con los niveles de almacenamiento realmente alcanzados. Si se dispone de pronóstico de caudales, se usa un procedimiento similar para seleccionar niveles de almacenamiento de las curvas-guías para los meses siguientes.
6. El archivo ORGANIZ para el Programa MODSIM se puede ahora editar para:
 - a. Iniciar; inicio del mes de almacenamiento en los embalses de Valdesia y Las Barrias (observe que las unidades son $10^3 M^3$) si la semana actual (en análisis) es la primera en el mes de análisis; de otra forma el valor correcto estará en el archivo.
 - b. Modificar las prioridades para los sectores de riego, cuando necesario.
 - c. Modificar las prioridades para los dos embalses (si deseado) y entrar las metas de los niveles de almacenamiento de las curvas-guías si la semana actual (en análisis) es la primera en el mes. De otra forma las metas de almacenamiento estarán correctas a menos que el operador quiera cambiarlas por alguna razón.
 - d. Para las semanas intermedias del mes, actualizar las metas de almacenamiento anteriores para niveles de almacenamiento realmente medidos.

Aunque el programa de edición del archivo ORGANIZ puede correr interactivamente, se recomienda que las correcciones se hagan con el editor EDLIN o cualquier otro editor, en consideración a que el número de correcciones es mínimo en comparación al tamaño total del archivo.

7. Ahora, corra la modalidad de edición en el MODSIM para la sección de ADATA. Este archivo requerirá actualización extensiva y correcciones selectivas que son de mucha utilidad. Aquí el usuario entra pronósticos sobre:
 - a. Caudales semanales
 - b. Demandas de riego semanales para cada sector
 - c. Horas de generación de turbina
 - d. Evaporación neta
8. Ahora se puede ejecutar el Programa MODSIM y obtener las metas semanales de descarga y energía. Se recomienda hacer varias corridas con el MODSIM para varios conjuntos de pronósticos y cambios de prioridad para propósitos de sensibilidad y análisis de compromiso.

6. EJEMPLO DEMOSTRATIVO

Las Figuras 6, 7, 8 y 9 muestran un ejemplo de como se puede obtener un set de 12 metas de almacenamiento semanal desde las curvas-guías óptimas, si se conocen los niveles actuales de almacenamiento, caudales anteriores y pronósticos futuros. Se seleccionó el último trimestre de 1984, comenzando en la semana 40. Observe que se necesita interpolación en la Figura 7. En las figuras siguientes para los meses sucesivos, las metas de almacenamiento para el final del mes anterior se entran como niveles de almacenamiento inicial para los meses futuros, asumiendo que estos niveles se pueden obtener. Observe en la Figura 8 que el pronóstico de noviembre cae entre las curvas en las Figuras 8 y 9, de tal manera que se requiere la transferencia de una figura a la otra.

Figura 6. REGLA OPERACIONAL PARA OCTUBRE (1)
 $Q(\text{Sept})$ mayor que $19.04 \text{ m}^3/\text{s}$

Caudal anterior en Sept.

Figura 7. REGLA OPERACIONAL PARA NOVIEMBRE (1)

$Q(\text{Oct})$ mayor que $16.74 \text{ m}^3/\text{s}$

Figura 8. REGLA OPERACIONAL PARA DICIEMBRE
 $Q(\text{Nov})$ menor que $18.91 \text{ m}^3/\text{s}$

Figura 9. REGLA OPERACIONAL PARA DICIEMBRE (1)

La Figura 10 da un ejemplo de una sesión de edición para el archivo ORGANIZ usando el editor EDLIN en microcomputador IBM. El archivo se llama DEMO.ORG. La Figura 11 muestra una demostración de una sesión de edición para el archivo ADATA para este ejemplo, cuyo nombre es DEMO.ADA.

Los caudales deben ser pronosticados. Aquí, se usan extrapolaciones de información histórica sólo para ilustración. Observe que las horas de turbina semanales son inicialmente fijadas en 50, pero estos pueden cambiarse fácilmente. Las tasas de evaporación están basadas en información histórica, lo cual se puede encontrar en el Volumen II: Operación Normal del Informe Final. Realmente, el usuario puede introducir cualquier valor pronosticado que parezca apropiado. Las demandas semanales de los sectores de riego se tomaron de la Tabla 4, pero, nuevamente, se puede usar un valor pronosticado.

La Figura 12 muestra como se hace la preparación para realmente correr el MODSIM. La salida completa para esta demostración se presenta en el Anexo D. Observe que no hay deficiencias y se cumplen las metas de almacenamiento y la salida de potencia es muy baja. En el Anexo D se incluye otra corrida donde las horas de generación se aumentaron con el objeto de aumentar la producción de energía.

7. ORGANIZACION PARA OPERACION NORMAL

Se propone el establecimiento de dos comités para ejecutar la operación del sistema de embalses de Valdesia. El Comité de Operación Normal para guiar la operación del sistema de embalses bajo condiciones normales y el Comité de Operación de Emergencia para ejecutar las acciones apropiadas durante condiciones de emergencia.

El Comité de Operación Normal servirá para guiar y supervisar la operación, equitativa y eficiente, del sistema de embalses de Valdesia bajo operación normal. Esto incluye condiciones tales como crecidas ordinarias y deficiencias de agua y sequía. Para mas detalles sobre la organización incluyendo responsabilidades, funciones, normas e instrucciones, consulte el Volumen V: Organización y Funciones para Operación del Sistema de Embalses de Valdesia del Informe Final.

Tabla 4. Uso Consuntivo medio semanal calculado para el subsistema de riego de Valdesia (m^3/S).

SEMANA	S. 1	S. 2	S. 3	S. 4	S. 5	S. 6	S. 7	S. 8	TOTAL

***** River Basin Simulation Package (Network Flow Algorithm) *****
Version : MODSIMX V2.51 (448K RAM) cSu Feb. 1986

If you want to STOP execution at any time, just press Ctrl-Break !
For continuing execution,
Please press <return> to continue.

***** Data Editing Mode *****

There are two data files required for MODSIMX :
one generated by subroutine SORGANZP.FOR (ORGANIZ)
and the other one by subroutine SADATA.FOR (ADATA)

Do you want to Create any new data file ? [Yes/No] Y

If you want the data to be saved on another diskette,
Please take out program diskette and insert the data diskette
just "before" entering the data file name.

***** ORGANIZ SECTION *****

Do you want to Create a new ORGANIZ Data file ? [Yes/No] N

***** Transfer to ADATA Section *****

***** ADATA SECTION. *****

Do you want to Creat a new ADATA Data file ? [Yes/No] Y
Type in a NEW file name for saving input data = DEMO.ADA
Coded Inflow, Demand, and Evap. File "DEMO.ADA" " Creation

ENTER: [0] If data in Year/Month basis
[1] If data in Quarter/Week basis
1
ENTER: Total No. of Network Nodes =
12
ENTER: Total No. of Reservoirs = 2
Beginning Calender of Simulation = 40
Ending Calender of Simulation = 40

ENTER: Total No. of Additional DEMAND Nodes
whose Demands are to be Entered here in ADATA and not in ORGANIZ. = 9
ENTER: Node No. of each Demand Node
4 5 6 7 8 9 10 11 12

```

Figura 11 (continuación)

Confirm :

4	5	6	7	8	9	10	11	12
---	---	---	---	---	---	----	----	----

Is that Correct [Yes/No] ? Y

ENTER: Total No. of Nodes where Unregulated inflow Occurs = 1

ENTER: Node No. of each Unreg. Inflow Node

1

Confirm :

1

Is that Correct [Yes/No] ? Y

ENTER: Total No. of Reservoirs which has Power Plant = 1

ENTER: Node No. of each Reservoir which has Power Plant

1

Confirm :

1

Is that Correct [Yes/No] ? Y

ENTER: Total No. of Reservoir with Net Evap. <> 0

(Note: Negative values indicate precip. rate > evap. rate) = 2

ENTER: Node No. of Reservoirs with Evap. <> 0

1 2

Confirm :

1 2

Is that Correct [Yes/No] ? Y

ENTER: Weekly Inflows for Node No. 1 of Quarter 40

7*15120 13300 4*11980

Confirm :

Is that Correct [Yes/No] ? Y

The Coded Version of this Data File is Stored on Disk File : DEMO.ADA

***** End of ADATA Section *****

Do you want to Create any new data file ? [Yes/No] N

Here, take out your data diskette, and insert the program(working) diskette

When you have finished,
 Please press return to continue.

***** End of Editing Mode *****

Next will be Echo Print of ORGANIZ data file

***** ECHOIT Section *****

Do you want to echo print any ORGANIZ data file [Yes/No] ? N

***** End of ECHOIT Section *****

Program MODSIMX can now be executed

If you made any mistake and would like to correct it,
 Type in "CTRL-BREAK" followed by "Y" to interrupt batch file execution.

After correction, Type "MODSIMX" to run the batch file again !

Strike a key when ready . . .

```

```
***** River Basin Simulation Package (Network Flow Algorithm) *****
Version : MODSIMX V2.51 (448K RAM) cSu Feb. 1986
```

```
If you want to STOP execution at any time, just press Ctrl-Break !
```

```
For continuing execution,
Please press <return> to continue.
```

```
***** Data Editing Mode *****
```

```
There are two data files required for MODSIMX :
one generated by subroutine SORGANZP.FOR (ORGANIZ)
and the other one by subroutine SADATA.FOR (ADATA)
```

```
Do you want to Create any new data file ? [Yes/No] N
```

```
***** End of Editing Mode *****
```

```
Next will be Echo Print of ORGANIZ data file ....
```

```
***** ECHOIT Section *****
```

```
Do you want to echo print any ORGANIZ data file [Yes/No] ? Y
```

Note:

Before typing in the data file name,
take out the program diskette and
insert the diskette with the ORGANIZ data file

Type in file names :

```
INPUT DATA FILE (edited by ORGANIZ) = DEMO.ORG
OUTPUT FILE (for storing echo print) = DEMO.ECH
```

Figura 12 (continuación)

Any other ORGANIZ data file to be echo printed [Yes/No] ?
 Write fault error writing device PRN
 Abort, Retry, Ignore? R
 NN

 Here, insert the PROBLEM SOLVING program diskette
 i.e., the working diskette No.2

After you finished,
 Please press <return> to continue.

***** End of ECHOIT Section *****

Program MODSIMX can now be executed

If you made any mistake and would like to correct it,
 Type in "CTRL-BREAK" followed by "Y" to interrupt batch file execution.

After correction, Type "MODSIMX" to run the batch file again !

Strike a key when ready . . .

***** MODSIMX Mode *****
 Do you want to execute MODSIMX ? [Y/N] Y

Remove program diskette and insert the diskette
 which includes data files and will store program output,
 just "before" typing in data file name

Type in file names :

INPUT DATA FILE 1 (edited by ORGANIZ) = DEMO.ORG
 INPUT DATA FILE 2 (edited by ADATA) = DEMO.ADA
 OUTPUT DATA FILE (for storing result) = DEMO.RES

- * Initialize all necessary variables
- * Read in ORGANIZ data file
- * Set up the network with all artificial nodes & linkages
- * System Operation Analysis :

Quarter : 40 Week = 1 2 3 4 5 6 7 8 9 10 11 12
 Output the results of current Quarter

***** End of MODSIMX Package Execution *****

Now remove your data/output diskette
 and insert the program diskette

Figura 12 (continuación)

When you have finished,
Please press <return> to continue.

If you want to create/edit data file, or reexecute MODSIMX again,
Please type "MODSIMX" after disk prompt, eg. A> MODSIMX

To see the output file, say "OUTPUT.RLT", DOS command TYPE will show
all content on screen by typing "TYPE OUTPUT.RLT".
To get output on line printer, "PRINT OUTPUT.RLT" can be used.
You may also print the file with "COPY OUTPUT.RLT PRN:".

REGLA OPERACIONAL PARA FENERO (1)

Q(Dic) mayor que $18.74 \text{ m}^3/\text{s}$ 

Almacenamiento al final de mes (MMC)

 $68 \text{ m}^3/\text{s}$

(2)

REGLA OPERACIONAL PARA ENERO

O(Dic) menor que $18.74 \text{ m}^3/\text{s}$ 

Almacenamiento al final de mes, MMC

(1)

REGLA OPERACIONAL PARA FEBRERO
O (Ene mayor que 15.30 M³/S

Almacenamiento al fin de mes MCM

(2)

REGLA OPERACIONAL PARA FEBRERO

Q(Ene) menor que 15.30 m^3/s 

Almacenamiento al final de mes , MCM

(1)

REGLA OPERACIONAL PARA MARZO
 $Q(\text{Feb})$ mayor que $14.52 \text{ m}^3/\text{s}$

Almacenamiento al fin de mes, MCM

(2)

REGLA OPERACIONAL PARA MARZO
 $Q_{(Feb)} \text{ menor que } 14.52 \text{ m}^3/\text{s}$

Almacenamiento al fin de mes, MCM

(1)

REGLA OPERACIONAL PARA ABRIL

(Q) Mar mayor que 12.93 M³/s

Almacenamiento al final de mes, MCM

— 14
— 18
- - - 22
— — 34 m³/s

REGLA OPERACIONAL PARA ABRIL
 Q (Mar) menor que $12.93 \text{ m}^3/\text{s}$

(2)

Almacenamiento al final de mes, MMC

(1)

REGLA OPERACIONAL PARA MAYO

Q(Abr) mayor que 12.28 m³/s

(2)

REGLA OPERACIONAL PARA MAYO

Q(Abr) menor que 12.28 m³/s

Almacenamiento al fin de mes (MMC)

REGLA OPERACIONAL PARA JUNIO (1)

$Q(\text{Mgy})$ mayor que $20.09 \text{ m}^3/\text{s}$

REGLA OPERACIONAL PARA JULIO
(1)

REGLA OPERACIONAL PARA JULIO (2)

 $Q(\text{Junio}) \text{ menor que } 19.86 \text{ m}^3/\text{s}$ 

(1)

REGLA OPERACIONAL PARA AGOSTO
 Q (Julio) mayor que $18.25 \text{ m}^3/\text{s}$

Almacenamiento a fin de mes (MMC)

(2)

REGLA OPERACIONAL PARA AGOSTO
 Q (Julio) menor que $18/25 \text{ m}^3/\text{s}$

(1)

REGLA OPERACIONAL PARA SEPTIEMBRE
 Q (Agosto) mayor que $24.80 \text{ m}^3/\text{s}$

(2)

REGLA OPERACIONAL PARA SEPTIEMBRE
Q (Agosto) menor que: 24.80 m^3/s

(1)

REGLA OPERACIONAL PARA OCTUBRE
 Q (sept.) mayor que $19.04 \text{ m}^3/\text{s}$

Almacenamiento al fin de mes (MMC)

(2)

REGLA OPERACIONAL PARA OCTUBRE
Q (Sept.) menor que 19.04 m^3/s

Almacenamiento al fin de mes (MMC)

18 m^3/s

(1)

REGLA OPERACIONAL PARA NOVIEMBRE

Q (oct.) mayor que $16.74 \text{ m}^3/\text{s}$ 

ALMACENAMIENTO AL FIN DE MES (MMC)

(2.)

REGLA OPERACIONAL PARA NOVIEMBRE

Q (Oct.) menor que $16.74 \text{ m}^3/\text{s}$ 

REGLA OPERACIONAL PARA NOVIEMBRE
